I think that this question should be closed and should be converted to a canonical answer. Recurrence patterns in localized prostate cancer treated with radical prostatectomy and radiation therapy. The patterns of failure after treatment of localized prostate cancer with either radical retropubic prostatectomy and pelvic lymphadenectomy or external beam radiotherapy were studied in 150 men treated with curative intent. The patients were treated at Stanford University Hospital and the affiliated Veterans Administration Hospital from 1970 to 1982. Both the retropubic and pelvic lymphadenectomy groups contained 38 patients with positive nodes, 37 of whom were treated postoperatively with prophylactic radiotherapy. The external beam radiotherapy group contained 122 patients who were treated with definitive therapy. The follow-up periods ranged from 2.5 to 12.3 years. The actuarial survival and local control probabilities at 5, 10, and 15 years were 95%, 93%, and 83%, and 90%, 94%, and 90%, respectively, for the retropubic surgery group, and 96%, 92%, and 92%, and 94%, 93%, and 93%, respectively, for the external beam radiotherapy group. The actuarial survival and local control probabilities at 5, 10, and 15 years were 92%, 87%, and 85%, and 77%, 76%, and 74%, respectively, for the positive lymph node subgroup and 99%, 98%, and 93%, and 96%, 94%, and 94%, respectively, for the negative node subgroup treated with radical retropubic prostatectomy. These results demonstrated that excellent survival and local control rates can be achieved with either modality. This study confirms that positive lymph nodes on final pathology after a clinically negative lymphadenectomy does not affect survival. The risk 2d92ce491b
